You are a Product Analyst investigating how delivery partners manage multiple order pickups....

Question 1: For all delivery routes between October 1st and December 31st, 2024, what percentage of routes had multiple (ie. 2 or more) order pickups? This metric will quantify how often order bundling occurs to help evaluate routing efficiency.

```
with total AS(  
    SELECT *,  
           CASE WHEN pickup_count >= 2 THEN 1 ELSE 0 END AS multiple  
FROM fct_delivery_routes  
WHERE route_date BETWEEN '2024-10-01' AND '2024-12-31')  
  
SELECT SUM(multiple)*100.0 / COUNT(*)  
FROM total
```

Question 2: For delivery routes with multiple pickups between October 1st and December 31st, 2024, how does the average delivery time differ between routes with exactly 2 orders and routes with 3 or more orders? Use a CASE statement to segment the routes accordingly. This analysis will clarify the impact of different levels of order clustering on delivery performance.

```
with total AS(
  SELECT *,
    CASE WHEN pickup_count = 2 THEN '2 orders'
         WHEN pickup_count >= 3 THEN 'Three or More Pickups'
         ELSE pickup_count::text END AS number_order
  FROM fct_delivery_routes
  WHERE route_date BETWEEN '2024-10-01' AND '2024-12-31')

SELECT number_order, avg(delivery_time) as avg_delivery_time
FROM total
WHERE number_order != '1'
GROUP BY number_order
```

Question 3: What is the average earnings per pickup across all routes?
Note: Some rows have missing values in the earnings column. Before calculating the final value, replace any missing earnings with the average earnings value.

```
with total AS(
  SELECT *,
    COALESCE(earnings, ROUND(CAST((SELECT AVG(earnings) FROM
fct_delivery_routes) AS numeric), 2)) AS fill
  FROM fct_delivery_routes)

SELECT SUM(fill) / SUM(pickup_count) AS average_per_pickup
FROM total
```
